

Summary of constraints on cosmic strings using data from the third Advanced LIGO-Virgo observing run

Mitchell Gerrard

University Of Southampton

What are cosmic strings?

- line-like 1D topological defects
- spontaneous symmetry-breaking phase transition
- an energy scale of around 10^{16}GeV and lower

What are cosmic strings?

- Cosmic strings are well-defined by the **Nambu-Goto string action**
- It is the starting point of the analysis of zero-thickness (infinitely thin) string behaviour
- principles of Lagrangian mechanics
- a relativistic string's action is proportional to the area of the sheet which the string traces as it travels through spacetime.

String tension

The dimensionless quantity of the string tension $G\mu$ parameterises these strings, with μ being the string linear mass density and G is Newton's gravitational constant. This is the value that constraints were obtained for. The string tension is also related to the energy scale η by $G\mu \sim (\frac{\eta}{M_{Plank}})^2$.

Why Look at gravitational waves for cosmic strings?

- Cosmic strings exist before recombination and the CMB. This means that there is a wall of electromagnetic waves that we cannot examine before the CMB.
- This means we need to look at gravitational waves to view items in this time period. Because there is no such wall for gravitational waves.

How are the Gravitational waves produced?

- A cosmic string network relaxes towards a scaling solution
- Typical loop lengths are proportional to cosmic time
- Infinitive strings reach these solutions by forming loops that cascade into smaller loops by emitting gravitational waves

Loop Cascade

How are the Gravitational waves produced?

- Cosmic string loops oscillate in time; these oscillations emit gravitational waves.
- Kinks are discontinuities in the tangent vector of the string that propagate at the speed of light. They appear in pairs due to collisions between two cosmic strings and are chopped off when a loop forms
- Cusps, which are short-lived, produce beamed gravitational waves in the forward direction
- When two kinks collide, it's expected to radiate gravitational waves isotropically

Kinks

How do these gravitational waves look?

- power of these gravitational waves that the loops produce is $P_{gw} = \Gamma_d G \mu^2$ and a decay lifetime $\frac{\ell}{\gamma_d}$
- γ_d is a numerical factor, ℓ is the invariant loop length and $\gamma_d = \Gamma_d G \mu^2$ is the gravitational-wave length scale measured in time.

How do these gravitational waves look?

The wave-forms have been calculated in [1, 2, 3] at a redshift z , we get our h being

$$h_i(\ell, z, f) = A_i(\ell, z) f^{q_i} \quad (1)$$

where $i = c, k, kk$ which identifies the different cases. The indices q are $q_c = \frac{4}{3}, q_k = \frac{5}{3}, q_{kk} = 2$ and then the amplitude will be

$$A_i(\ell, z) = g_{1,i} \frac{G\mu\ell^{2-q_i}}{(1+z)^{q_i-1} r(z)} \quad (2)$$

where $r(z)$ is the comoving distance to the loop and the prefactor $g_{1,i}$ taking 3 different numerical values for each case
 $g_{1,c} \approx 0.85, g_{1,k} \approx 0.29, g_{1,kk} \approx 0.10$

What are they looking for?

These are discussed in the context of numerical simulations of [4, 5] and they develop an interpolation between the two. From these, they developed the burst rate of the gravitational waves and the energy density spectra using the O3 data from LIGO and Virgo. They also use a stochastic search combining the sensitivities of the searches to constrain the string tension.

Burst Search

The burst search uses three main steps,

- a matched filter search using the waveform in Eq 1.
- Then the candidates are filtered through for the ones in more than one detector within a time window accounting for the difference in the gravitational-wave arrival time between detectors.
- Finally, double and triple-coincident events are ranked using a likelihood function $\Lambda(x)$, where x is a set of parameters used to discriminate true cosmic string signals from noise. The burst search is performed separately for cusps, kinks and kink-kink collision waveforms.

Burst Search

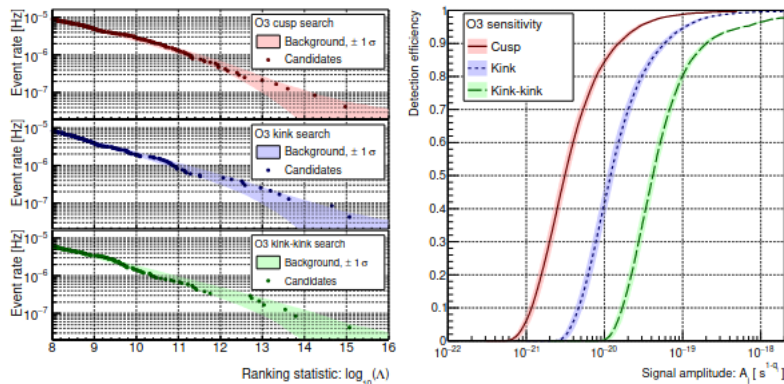

FIG. 2. Left panel: cumulative distribution of cosmic string burst candidate events produced by cusps (top), kinks (middle) and kink-kink collisions (bottom). The expected distributions from background noise are represented by $\pm 1\sigma$ shaded areas. Right panel: the detection efficiency is measured using simulated signals, as a function of the signal amplitude for cusps, kinks and kink-kink collisions. Note that the horizontal axis measures different amplitude quantities, A_i , for the three types of signals, parameterized by the waveform frequency power law q_i .

$$1.7 \times 10^6 (G\mu/10^{-10})^{-\frac{3}{2}} \text{light years at redshift 100}$$

The incoherent superposition of bursts from loops with all possible sizes through the history of the Universe produces a stochastic gravitational wave background [6]. The normalized energy density of which is defined as

$$\Omega_{GW}(f) = \frac{f}{\rho_c} \frac{d\rho_{GW}}{df} \quad (4)$$

where $\rho_c = \frac{3H_0^2 c^2}{8\pi G}$

The authors used data from this run and the first two for this search. The results reported in [7] assume the normalized energy density of the stochastic background, Eq 4, to be a power-law α of the frequency:

$$\Omega_{GW}(f) = \Omega_{ref} \left(\frac{f}{f_{ref}} \right)^\alpha \quad (5)$$

where f_{ref} denotes a reference frequency, fixed to 25Hz. LIGO and Virgo did not detect a stochastic background, and so set upper limits depending on the value of α . The upper bound of this background is $\Omega_{GW} \leq 5.8 \times 10^{-9}$ for a flat background $\alpha = 0$.

FIG. 1. Predictions of the gravitational-wave energy density spectra using different models for the loop distribution function $n(\gamma, z)$ and varying the number of kinks per loop oscillation N_k . The string tension $G\mu$ is fixed to 10^{-8} . Top-left: model **A**, $N_k = 100$. Top-right: model **B**, $N_k = 100$. Bottom-left: model **C-1**, $N_k = 1$. Bottom-right: model **C-1**, $N_k = 100$. For model **C-1**, we use the following model parameters (see Supplemental Material): $\chi_{\text{rad}} = 0.45$, $\chi_{\text{mat}} = 0.295$, $c_{\text{rad}} = 0.15$, $c_{\text{mat}} = 0.019$; the subscripts refer to the radiation and matter eras, respectively. We also show the energy density spectra of the three different components and 2- σ power-law integrated (PI) curves [40] for the O3 isotropic stochastic search [27], and projections for the HLV network at design sensitivity, and the A+ detectors [41].

The upper bound is $G\mu \leq 10^{-6}$ coming from the cosmic microwave background measurements [8, 9, 10, 11].

Stochastic Search

constraints on $G\mu$. model A, $G\mu \leq (9.6 \times 10^{-9} - \times 10^{-6})$.

model B: $G\mu \leq (4.0 - 6.3) \times 10^{-15}$.

model C-1 $G\mu \leq (4.0 - 6.3) \times 10^{-15}$.

model C-2: $G\mu \leq (4.2 - 7.0) \times 10^{-15}$.

$$G\mu \lesssim 4 \times 10^{-15} \quad (6)$$
